

rootbeer Executive Summary

Kyle Rainey

Rootbeer is an Android library for checking if the current device is rooted. This document is a brief review of the development history.

Rootbeer does not seem to be an extremely active project. After an initial spurt of development, the rate of commits seemed to slow down drastically. Most of the commits, especially the recent commits, are from the founder of the project, Scott Alexander-Brown (the gray dot in the scatterplot). However, recently there have been a few commits from Artsem Kurantsou. So it is possible that this project may become more active in the future.

Useful git Commands

In doing this lab, I thought the most helpful git command was git branch. Creating branches allows you to keep your changes for a new features separate from the main branch, which seems extremely helpful for organization.
